

Chapel: Base Language

Goals of this Talk

- Help you understand code in subsequent slide decks
- Give you the basic skills to program in Chapel today
- Provide a survey of Chapel's base language features
- Impart an appreciation for the base language design

Note: *There is more in this slide deck than we will be able to cover, so consider it a reference and overview*

"Hello World" in Chapel: Two Versions

- Fast prototyping

```
writeln("Hello, world!");
```

- "Production-grade"

```
module HelloWorld {
  def main() {
    writeln("Hello, world!");
  }
}
```

Characteristics of Chapel

- **Syntax**
 - Basics taken from C and Modula
 - Influences from several other languages
- **Semantics**
 - Imperative, block-structured execution model
 - Optional object-oriented programming
 - Type inference for convenience and generic programming
 - Static typing for performance and safety
- **Design points**
 - No pointers and limited aliases
 - No compiler-inserted array temporaries
 - Intentionally not an extension of an existing language

Chapel Influences

ZPL, HPF: data parallelism, index sets, distributed arrays

CRAY MTA C/Fortran: task parallelism, synchronization

CLU (see also Ruby, Python, C#): iterators

Scala (see also ML, Matlab, Perl, Python, C#): type inference

Java, C#: OOP, type safety

C++: generic programming/templates
(but with a different syntax)

Outline

- Introductory Notes
- Elementary Concepts
 - Lexical structure
 - Types, variables, and constants
 - Operators and Assignments
 - Compound Statements
 - Input and output
- Data Types and Control Flow
- Program Structure

Lexical Structure

- Comments

```
/* standard
  C style
  multi-line */

// standard C++ style single-line
```

- Identifiers:

- Composed of A-Z, a-z, _, \$, 0-9
 - Cannot start with 0-9
- Case-sensitive

Primitive Types

Type	Description	Default Value	Currently-Supported Bit Widths	Default Bit Width
bool	logical value	false	8, 16, 32, 64	impl. dep.
int	signed integer	0	8, 16, 32, 64	32
uint	unsigned integer	0	8, 16, 32, 64	32
real	real floating point	0.0	32, 64	64
imag	imaginary floating point	0.0i	32, 64	64
complex	complex floating points	0.0 + 0.0i	64, 128	128
string	character string	""	any multiple of 8	N/A

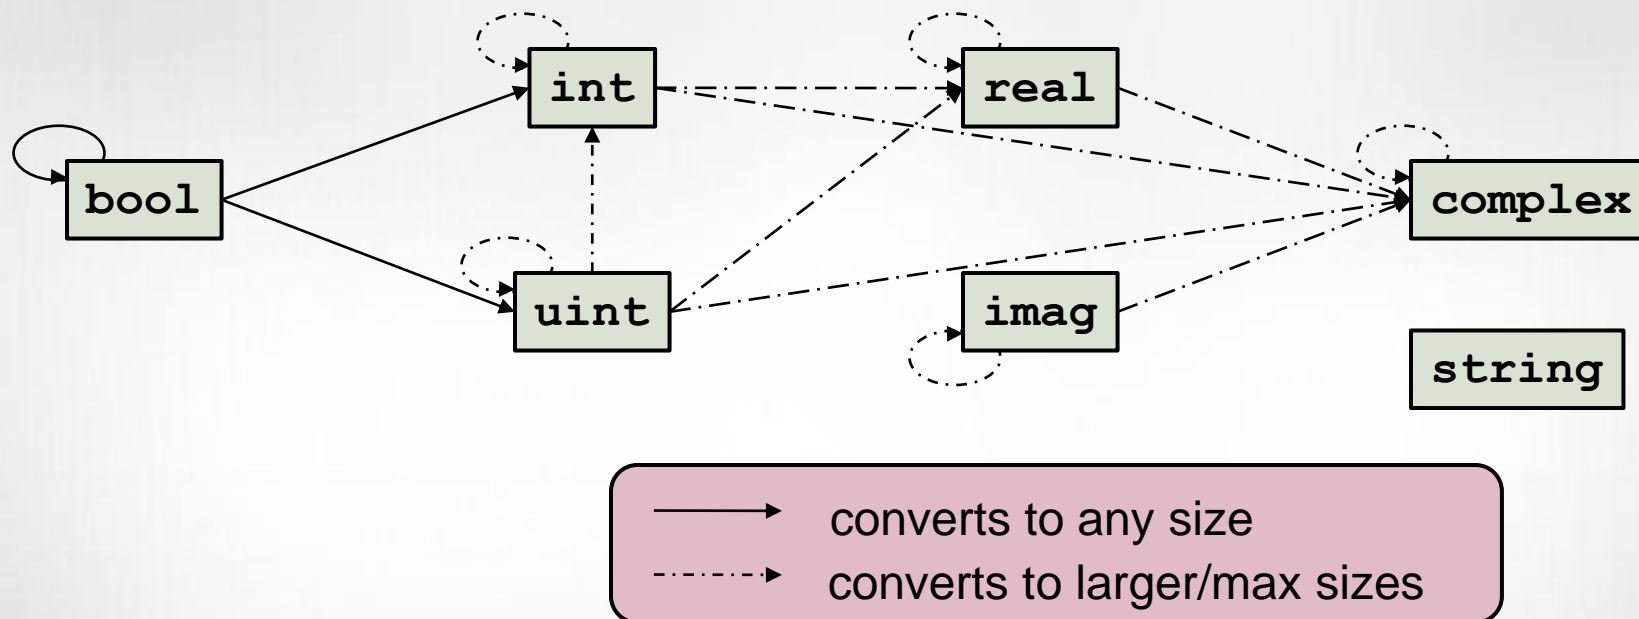

• Syntax

```
primitive-type:
  type-name [ ( bit-width ) ]
```

• Examples

```
int (64)    // 64-bit int
real (32)   // 32-bit real
uint       // 32-bit uint
```

Implicit Type Conversions (Coercions)

Notes:

- reals do not implicitly convert to ints as in C
- ints and uints don't interconvert as handily as in C
- C# has served as our guide in establishing these rules

Type Aliases and Casts

- Basic Syntax

```
type-alias-declaration:
    type identifier = type-expr;

cast-expr:
    expr : type-expr
```

- Semantics

- type aliases are simply symbolic names for types
- casts are supported between any primitive types

- Examples

```
type elementType = complex(64);

5:int(8)    // store value as int(8) rather than int(32)
"54":int    // convert string to an int(32)
249:elementType // convert int to complex(64)
```

Variables, Constants, and Parameters

- Basic syntax

declaration:

```
var    identifier [: type] [= init-expr];
const identifier [: type] [= init-expr];
param identifier [: type] [= init-expr];
```

- Semantics

- var/const**: execution-time variable/constant
- param**: compile-time constant
- No *init-expr* \Rightarrow initial value is the type's default
- No *type* \Rightarrow type is taken from *init-expr*

- Examples

```
const pi: real = 3.14159;
var count: int;           // initialized to 0
param debug = true;       // inferred to be bool
```

Config Declarations

- Syntax

```
config-declaration:
  config type-alias-declaration
  config declaration
```

- Semantics

- Like normal, but supports command-line overrides
- Must be declared at module/file scope

- Examples

```
config param intSize = 32;
config type elementType = real(32);
config const epsilon = 0.01:elementType;
config var start = 1:int(intSize);
```

```
% chpl myProgram.chpl -sintSize=64 -selementType=real
% a.out --start=2 --epsilon=0.00001
```

Basic Operators and Precedence

Operator	Description	Associativity	Overloadable
:	cast	left	no
**	exponentiation	right	yes
! ~	logical and bitwise negation	right	yes
* / %	multiplication, division and modulus	left	yes
<i>unary</i> + -	positive identity and negation	right	yes
+ -	addition and subtraction	left	yes
<< >>	shift left and shift right	left	yes
<= >= < >	ordered comparison	left	yes
== !=	equality comparison	left	yes
&	bitwise/logical and	left	yes
^	bitwise/logical xor	left	yes
	bitwise/logical or	left	yes
&&	short-circuiting logical and	left	via isTrue
	short-circuiting logical or	left	via isTrue

Assignments

Kind	Description
=	simple assignment
+= -= *= /= %= **= &= = ^= &&= = <<= >>=	compound assignment (<i>e.g.</i> , <code>x += y;</code> is equivalent to <code>x = x + y;</code>)
<=>	swap assignment

- Note: assignments are only supported at the statement level

Compound Statements

- Syntax

```
compound-stmt:
  { stmt-list }
```

- Semantics

- As in C, permits a series of statements to be used in place of a single statement

- Example

```
{
  writeln("Starting a compound statement");
  x += 1;
  writeln("Ending the compound statement");
}
```

Console Input/Output

- **Output**

- `write(expr-list)`: writes the argument expressions
- `writeln(...)` variant: writes a linefeed after the arguments

- **Input**

- `read(expr-list)`: reads values into the argument expressions
- `read(type-list)`: reads values of given types, returns as tuple
- `readln(...)` variant: same, but reads through next linefeed

- **Example:**

```
var first, last: string;  
write("what is your name? ");  
read(first);  
last = read(string);  
writeln("Hi ", first, " ", last);
```

```
What is your name?  
Chapel User  
Hi Chapel User
```

- I/O to files and strings also supported

Outline

- Introductory Notes
- Elementary Concepts
- Data Types and Control Flow
 - Tuples
 - Ranges
 - Arrays
 - For loops
 - Other control flow
- Program Structure

Tuples

- Syntax

```
heterogeneous-tuple-type:
  ( type, type-list )
```

```
homogenous-tuple-type:
  param-int-expr * type
```

```
tuple-expr:
  ( expr, expr-list )
```

- Purpose

- supports lightweight grouping of values
(e.g., when passing or returning procedure arguments)

- Examples

```
var coord: (int, int, int) = (1, 2, 3);
var coordCopy: 3*int = i3;
var (i1, i2, i3) = coord;
var triple: (int, string, real) = (7, "eight", 9.0);
```

Range Values

- Syntax

```
range-expr:
  [low] .. [high]
```

- Semantics

- Regular sequence of integers

low ≤ *high*: *low*, *low*+1, *low*+2, ..., *high*

low > *high*: degenerate (an empty range)

low or *high* unspecified: unbounded in that direction

- Examples

```
1..6           // 1, 2, 3, 4, 5, 6
6..1           // empty
3..            // 3, 4, 5, 6, 7, ...
```

Range Operators

- Syntax

```

range-op-expr:
  range-expr by stride
  range-expr # count
  range-expr (range-expr)
  
```

- Semantics

- by**: strides range; negative *stride* \Rightarrow start from *high*
- #**: selects initial *count* elements of range
- ()** or **[]**: intersects the two ranges

- Examples

```

1..6 by 2      // 1, 3, 5
1..6 by -1     // 6, 5, 4, ..., 1
1..6 #4        // 1, 2, 3, 4
1..6[3..]      // 3, 4, 5, 6
  
```

```

1.. by 2      // 1, 3, 5, ...
1.. by 2 #3   // 1, 3, 5
1.. #3 by 2   // 1, 3
0..#n         // 0, ..., n-1
  
```

Array Types

- Syntax

```
array-type:
  [ index-set-expr ] elt-type
```

- Semantics

- Stores an element of *elt-type* for each index
- May be initialized using tuple expressions

- Examples

```
var A: [1..3] int = (5, 3, 9), // 3-element array of ints
    B: [1..3, 1..5] real,      // 2D array of reals
    C: [1..3][1..5] real;      // array of arrays of reals
```

Much more on arrays in the data parallelism talk...

For Loops

- Syntax

```
for-loop:
  for index-expr in iteratable-expr { stmt-list }
```

- Semantics

- Executes loop body serially, once per loop iteration
- Declares new variables for identifiers in *index-expr*
 - type and const-ness determined by *iteratable-expr*
 - iteratable-expr* could be a range, array, or iterator

- Examples

```
var A: [1..3] string = (" DO", " RE", " MI");

for i in 1..3 { write(A(i)); }           // DO RE MI
for a in A { a += "LA"; } write(A);     // DOLA RELA MILA
```

Zipper and Tensor Iteration

- Syntax

```

zipper-for-loop:
  for index-expr in ( iteratable-exprs ) { stmt-list }

tensor-for-loop:
  for index-expr in [ iteratable-exprs ] { stmt-list }
  
```

- Semantics

- Zipper iteration is over all yielded indices pair-wise
- Tensor iteration is over all pairs of yielded indices

- Examples

```

for i in (1..2, 0..1) { ... } // (1,0), (2,1)

for i in [1..2, 0..1] { ... } // (1,0), (1,1), (2,0), (2,1)
  
```

Other Control Flow Statements

- Conditional statements

```
if cond { computeA(); } else { computeB(); }
```

- While loops

```
while cond {  
  compute();  
}
```

```
do {  
  compute();  
} while cond;
```

- Select statements

```
select key {  
  when value1 { compute1(); }  
  when value2 { compute2(); }  
  otherwise    { compute3(); }  
}
```

Note: *Chapel also has expression-level conditionals and for loops*

Control Flow: Braces vs. Keywords

Note: *Most control flow supports keyword-based forms for single-statement versions*

- Conditional statements

```
if cond then computeA(); else computeB();
```

- While loops

```
while cond do  
  compute();
```

- For loops

```
for indices in iteratable-expr do  
  compute();
```

- Select statements

```
select key {  
  when value1 do compute1();  
  when value2 do compute2();  
  otherwise do compute3();  
}
```

Outline

- Introductory Notes
- Elementary Concepts
- Data Types and Control Flow
- Program Structure
 - Procedures and iterators
 - Modules and `main()`
 - Records and classes
 - Generics
 - Other basic language features

Procedures, by example

- Example to compute the area of a circle

```
def area(radius: real): real {
  return 3.14 * radius**2;
}
```

```
writeln(area(2.0));    // 12.56
```

```
def area(radius = 0.0) {
  return 3.14 * radius**2;
}
```

Argument and return types can be omitted

- Example of argument default values, naming

```
def writeCoord(x: real = 0.0, y: real = 0.0) {
  writeln((x,y));
}
```

```
writeCoord(2.0);           // (2.0, 0.0)
writeCoord(y=2.0);         // (0.0, 2.0)
writeCorrd(y=2.0, 3.0);    // (3.0, 2.0)
```

Iterators

- **Iterator:** a procedure that generates values/variables
 - Used to drive loops or populate data structures
 - Like a procedure, but yields values back to invocation site
 - Control flow logically continues from that point
- **Example**

```
def fibonacci(n: int) {
  var current = 0,
      next = 1;
  for 1..n {
    yield current;
    current += next;
    current <=> next;
  }
}
```

```
for f in fibonacci(7) do
  writeln(f);
```

```
0
1
1
2
3
5
8
```

Argument and Return Intents

- Arguments can optionally be given intents
 - (blank): varies with type; follows principle of least surprise
 - most types: **const**
 - arrays, domains, sync vars: passed by reference
 - **const**: disallows modification of the formal
 - **in**: copies actual into formal at start; permits modifications
 - **out**: copies formal into actual at procedure return
 - **inout**: does both of the above
 - **param/type**: formal must be a param/type (evaluated at compile-time)
- Returned values are **const** by default
 - **const**: cannot be modified (without assigning to a variable)
 - **var**: permits modification back at the callsite
 - **type**: returns a type (evaluted at compile-time)
 - **param**: returns a param value (evaluated at compile-time)

Modules

- **Syntax**

```

module-def:
  module identifier { code }

module-use:
  use module-identifier;
  
```

- **Semantics**

- all Chapel code is stored in modules
- using a module makes its symbols visible in that scope
- module-level statements are executed at program startup
 - useful for initializing a module
- for convenience, a file with top-level code defines a module with the file's name

Program Entry Point: main()

• Semantics

- Chapel programs start by:
 - initializing all modules
 - executing main(), if it exists
- Any module may define a main() procedure
- If multiple modules define main(), the user must select one

```
M1.chpl:
use M2;
writeln("Init-ing M1");
def main() { writeln("Running M1"); }
```

```
M2.chpl:
module M2 {
  use M1;
  writeln("Init-ing M2");
  def main() { writeln("Running M2"); }
}
```

```
% chpl M1.chpl M2.chpl \
  --main-module M1
```

```
% ./a.out
```

```
Init-ing M2
Init-ing M1
Running M1
```

Revisiting "Hello World"

- Fast prototyping

hello.chpl

```
writeln("Hello, world!");
```

==

```
module hello {  
  writeln("Hello, world!");  
}
```

- "Production-grade"

```
module HelloWorld {  
  def main() {  
    writeln("Hello, world!");  
  }  
}
```

Module-level code is
executed during module
initialization

main() executed when
program begins running

Records and Classes

- Chapel's struct/object types
 - Contain variable definitions (fields)
 - Contain procedure & iterator definitions (methods)
 - Records: value-based (*e.g.*, assignment copies fields)
 - Classes: reference-based (*e.g.*, assignment aliases object)
 - Record:Class :: C++ class:Java class
- Example

```
record circle {
  var radius: real;
  def area() {
    return pi*radius**2;
  }
}
```

```
var c1, c2: circle;
c1 = new c1(radius=1.0);
c2 = c1;           // copies c1
c1.radius = 5.0;
writeln(c2.radius); // 1.0
// records deleted by compiler
```

Records and Classes

- Chapel's struct/object types
 - Contain variable definitions (fields)
 - Contain procedure & iterator definitions (methods)
 - Records: value-based (*e.g.*, assignment copies fields)
 - Classes: reference-based (*e.g.*, assignment aliases object)
 - Record:Class :: C++ class:Java class
- Example

```
class circle {
  var radius: real;
  def area() {
    return pi*radius**2;
  }
}
```

```
var c1, c2: circle;
c1 = new c1(radius=1.0);
c2 = c1;  // aliases c1's circle
c1.radius = 5.0;
writeln(c2.radius);  // 5.0
delete c1;
```

Method Examples

Methods are procedures associated with types

```
def circle.circumference
  return 2* pi * radius;

writeln(c1.area(), " ", c1.circumference);
```

Methods can be defined for any type

```
def int.square()
  return this**2;

writeln(5.square());
```

Generic Procedures

Generic procedures can be defined using type and param arguments:

```
def foo(type t, x: t) { ... }
def bar(param bitWidth, x: int(bitWidth)) { ... }
```

Or by simply omitting an argument type (or type part):

```
def goo(x, y) { ... }
def sort(A: []) { ... }
```

Generic procedures are instantiated for each unique argument signature:

```
foo(int, 3);           // creates foo(x:int)
foo(string, "hi");    // creates foo(x:string)
goo(4, 2.2);          // creates goo(x:int, y:real)
```

Generic Objects

Generic objects can be defined using type and param fields:

```
class Table { param size: int; var data: size*int; }
class Matrix { type eltType; ... }
```

Or by simply eliding a field type (or type part):

```
record Triple { var x, y, z; }
```

Generic objects are instantiated for each unique type signature:

```
// instantiates Table, storing data as a 10-tuple
var myT: Table(10);
// instantiates Triple as x:int, y:int, z:real
var my3: Triple(int, int, real) = new Triple(1, 2, 3.0);
```

Other Base Language Features not covered today

- Enumerated types
- Unions
- Type select statements, argument type queries
- Parenthesis-less functions/methods
- Procedure dispatch constraints (where clauses)
- Compile-time features for meta-programming
 - type/param procedures
 - folded conditionals
 - unrolled for loops
 - user-defined compile-time warnings and errors

Status: Base Language Features

- Most features are in reasonably good shape
- Performance is currently lacking in some cases
- Some semantic checks are incomplete
 - e.g., constness-checking for members, arrays
- Error messages could use improvement at times
- OOP features are limited in certain respects
 - multiple inheritance
 - user constructors for generic classes, subclasses
- Memory for strings is currently leaked

Future Directions

- Fixed-length strings
- I/O improvements
 - Binary I/O
 - Parallel I/O
 - General serialization capability
- Exceptions
- Interfaces
- Namespace control
 - private fields/methods in classes and records
 - module symbol privacy, filtering, renaming
- Interoperability with other languages
